NAG Fortran Library Routine Document

F07AAF (DGESV)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1   Purpose

F07AAF (DGESV) computes the solution to a real system of linear equations

$$AX = B,$$

where A is an n by n matrix and X and B are n by r matrices.

2   Specification

```
SUBROUTINE F07AAF (N, NRHS, A, LDA, IPIV, B, LDB, INFO)
INTEGER           N, NRHS, LDA, IPIV(*), LDB, INFO
double precision  A(LDA,*), B(LDB,*)
```

The routine may be called by its LAPACK name **dgesv**.

3   Description

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = PLU,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $AX = B$.

4   References

Golub G H and Van Loan C F (1996) *Matrix Computations* (3rd Edition) Johns Hopkins University Press, Baltimore

5   Parameters

1:    N – INTEGER   *Input*

  On entry: n, the number of linear equations, i.e., the order of the matrix A.

  Constraint: $N \geq 0$.

2:    NRHS – INTEGER   *Input*

  On entry: r, the number of right-hand sides, i.e., the number of columns of the matrix B.

  Constraint: $NRHS \geq 0$.

3:    A(LDA,∗) – **double precision** array   *Input/Output*

  Note: the second dimension of the array A must be at least $\max(1, N)$.

  On entry: the n by n coefficient matrix A.

On exit: the factors L and U from the factorization $A = PLU$; the unit diagonal elements of L are not stored.

4:    LDA – INTEGER   *Input*

On entry: the first dimension of the array A as declared in the (sub)program from which F07AAF (DGESV) is called.

Constraint: $\text{LDA} \geq \max(1, N)$.

5:    IPIV(∗) – INTEGER array   *Output*

Note: the dimension of the array IPIV must be at least $\max(1, N)$.

On exit: if $\text{INFO} \geq 0$, the pivot indices that define the permutation matrix P; at the ith step row i of the matrix was interchanged with row $\text{IPIV}(i)$. $\text{IPIV}(i) = i$ indicates a row interchange was not required.

6:    B(LDB,∗) – ***double precision*** array   *Input/Output*

Note: the second dimension of the array B must be at least $\max(1, \text{NRHS})$.

On entry: the n by r right-hand side matrix B.

On exit: if $\text{INFO} = 0$, the n by r solution matrix X.

7:    LDB – INTEGER   *Input*

On entry: the first dimension of the array B as declared in the (sub)program from which F07AAF (DGESV) is called.

Constraint: $\text{LDB} \geq \max(1, N)$.

8:    INFO – INTEGER   *Output*

On exit: $\text{INFO} = 0$ unless the routine detects an error (see Section 6).

6   Error Indicators and Warnings

Errors or warnings detected by the routine:

$\text{INFO} < 0$

If $\text{INFO} = -i$, the ith argument had an illegal value. An explanatory message is output, and execution of the program is terminated.

$\text{INFO} > 0$

If $\text{INFO} = i$, u_{ii} is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

7   Accuracy

The computed solution for a single right-hand side, $\hat{x}$, satisfies the equation of the form

$$(A + E)\hat{x} = b,$$

where

$$\|E\|_1 = O(\epsilon)\|A\|_1$$

and ϵ is the ***machine precision***. An approximate error bound for the computed solution is given by

$$\frac{\|\hat{x} - x\|_1}{\|x\|_1} \leq \kappa(A)\frac{\|E\|_1}{\|A\|_1}$$

where $\kappa(A) = \left\|A^{-1}\right\|_1 \|A\|_1$, the condition number of A with respect to the solution of the linear equations. See Section 4.4 of Anderson *et al.* (1999) for further details.

Following the use of F07AAF (DGESV), F07AGF (DGECON) can be used to estimate the condition number of A and F07AHF (DGERFS) can be used to obtain approximate error bounds. Alternatives to F07AAF (DGESV), which return condition and error estimates directly are F04BAF and F07ABF (DGESVX).

8   Further Comments

The total number of floating-point operations is approximately $\frac{2}{3}n^3 + 2n^2 r$, where r is the number of right-hand sides.

The complex analogue of this routine is F07ANF (ZGESV).

9   Example

To solve the equations

$$Ax = b,$$

where A is the general matrix

$$A = \begin{pmatrix} 1.80 & 2.88 & 2.05 & -0.89 \\ 5.25 & -2.95 & -0.95 & -3.80 \\ 1.58 & -2.69 & -2.90 & -1.04 \\ -1.11 & -0.66 & -0.59 & 0.80 \end{pmatrix}$$

and

$$b = \begin{pmatrix} 9.52 \\ 24.35 \\ 0.77 \\ -6.22 \end{pmatrix}.$$

Details of the LU factorization of A are also output.

9.1   Program Text

Note: the listing of the example program presented below uses ***bold italicised*** terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
